

# Koopman Operator Theory

The main objective of building the field of Koopman Operator Theory is to obtain linear representations of non-linear dynamical systems.

## 1 Background on Dynamical Systems

### 1.1 Dynamical Systems

**Definition 1 (Dynamical system).** A *dynamical system* on a manifold  $M$  is a  $\mathcal{C}^1$ -map

$$\phi : \mathbb{R} \times M \rightarrow M \quad (1)$$

where  $M \in \tau_{\mathbb{R}^n}$  and if  $\phi_t(x) = \phi(t, x)$ , then  $\phi_t$  satisfies

1.  $\phi_0(x) = x$  for all  $x \in M$  and
2.  $\phi_t \circ \phi_s(x) = \phi_{t+s}(x)$  for all  $s, t \in \mathbb{R}$  and  $x \in M$ .

We can easily see that for each  $t \in \mathbb{R}$ ,  $\phi_t$  is a  $\mathcal{C}^1$ -map of  $M$  into  $M$  which has a  $\mathcal{C}^1$ -inverse given by  $\phi_{-t}$ . Therefore,  $\phi = \{\phi_t\}_{t \in \mathbb{R}}$  is a one-parameter family of diffeomorphism on  $M$  that form a commutative group under composition.

For example, if  $A \in M^{n \times n}(\mathbb{R})$  then  $\phi(t, x) = e^{At}x$  defines a dynamical system on  $\mathbb{R}^n$  and for each  $x_0 \in \mathbb{R}^n$ ,  $\phi(t, x_0)$  is the solution of the initial value problem

$$\begin{aligned} \dot{x} &= Ax \\ x(0) &= x_0. \end{aligned} \quad (2)$$

In general, if  $\phi(t, x)$  is a dynamical system on  $M \subseteq \mathbb{R}^n$ , then

$$f(x) = \left. \frac{d}{dt} \phi(t, x) \right|_{t=0} \quad (3)$$

defines a  $\mathcal{C}^1$ -**vector field** on  $M$  and for each  $x_0 \in M$ ,  $\phi(t, x_0)$  is the solution of the initial value problem

$$\begin{aligned} \frac{d}{dt} x(t) &= f(x(t)) \\ x(0) &= x_0. \end{aligned} \quad (4)$$

## 1.2 Dynamical systems via differential equations

As we've seen in section 1.1, a dynamical system  $\phi$  defines a vector field  $\mathbf{f}$  and  $\phi(t, x_0)$  is the solution to a system of differential equation depending on  $\mathbf{f}$ . Therefore, it makes sense to define dynamical systems in terms of the corresponding differential equations.

**Definition 2 (Continuous-time dynamical system).** *A continuous-time dynamical system  $\phi(t, x) : \mathbb{R} \times M \rightarrow M$  is the solution to a system of differential equations*

$$\begin{aligned} \frac{d}{dt} \mathbf{x}(t) &= \mathbf{f}(\mathbf{x}, t; \beta) \\ \mathbf{x}(0) &= \mathbf{x}_0, \end{aligned} \tag{5}$$

where  $\mathbf{x}$  is the state of the dynamical system,  $\mathbf{f}$  defines a vector field on  $M$ ,  $t$  is the time index and  $\beta$  is a set of parameters.

It is possible to obtain the more general notion of a discrete-time dynamical system by discretizing the continuous time index set  $\{t\}_{t \in \mathbb{R}}$  into a discrete time index set  $\{k\Delta t\}_{k \in \mathbb{Z}}$ , where  $\Delta t$  is a fixed-length interval. Since by definition of derivative,

$$\begin{aligned} \dot{\mathbf{x}} &= \lim_{\Delta t \rightarrow 0} \frac{\mathbf{x}_{k+1} - \mathbf{x}_k}{\Delta t} \\ \dot{\mathbf{x}} &= \mathbf{f}(\mathbf{x}, t; \beta) \end{aligned} \tag{6}$$

it follows that

$$\mathbf{x}_{k+1} = \mathbf{x}_k + \int_{k\Delta t}^{(k+1)\Delta t} \mathbf{f}(\mathbf{x}(\tau)) d\tau = \dots = \mathbf{x}_0 + \int_0^{(k+1)\Delta t} \mathbf{f}(\mathbf{x}(\tau)) d\tau. \tag{7}$$

**Definition 3 (Discrete-time dynamical system).** *A discrete-time dynamical system is defined by the equation*

$$\mathbf{x}_{k+1} = F \mathbf{x}_k, \tag{8}$$

for which it holds,

$$\mathbf{x}_{k+1} = \mathbf{x}_k + \int_{k\Delta t}^{(k+1)\Delta t} \mathbf{f}(\mathbf{x}(\tau)) d\tau. \tag{9}$$

This defines a discrete-time propagator  $\mathbf{F}_{\Delta t}$  which gives rise to a flow map.

**Definition 4 (Flow map).** *A flow map is a function  $F_t$  which satisfies*

$$F_t(\mathbf{x}(t_0)) = \mathbf{x}(t_0) + \int_{t_0}^{t_0+t} \mathbf{f}(\mathbf{x}(\tau)) d\tau. \tag{10}$$

The flow map describes the evolution of measurements of the dynamical system given its corresponding state and vector field.

### 1.3 Linear dynamics and spectral decomposition

Consider a linear system of differential equations of the form

$$\dot{\mathbf{x}} = A\mathbf{x} \quad (11)$$

where  $\mathbf{x} \in \mathbb{R}^n$ ,  $A \in M^{n \times n}(\mathbb{R})$  and

$$\dot{\mathbf{x}} = \frac{d\mathbf{x}}{dt} = \begin{bmatrix} \frac{dx_1}{dt} \\ \frac{dx_2}{dt} \\ \vdots \\ \frac{dx_n}{dt} \end{bmatrix} \quad (12)$$

It is well-known that equation (11) has solution

$$\mathbf{x}(t_0 + t) = e^{At}\mathbf{x}(t_0). \quad (13)$$

Before we delve into the spectral decomposition theory, we should define the notion of eigenvalue and eigenvector.

**Definition 5 (Eigenvector/Eigenvalue).** Let  $\alpha : \mathbb{R}^n \rightarrow \mathbb{R}^n$  be a linear map with associated matrix  $A$ . Then,  $x \neq 0$  is an **eigenvector** of  $A$  if

$$Ax = \lambda x, \quad (14)$$

where  $\lambda$  is the associated **eigenvalue**.

The dynamics are completely determined by the eigenvalues and eigenvectors of  $A$ , given by the spectral decomposition  $AT = T\Lambda$ . But how can we find the eigenvectors and eigenvalues?

**Definition 6 (Characteristic equation).** The **characteristic polynomial** of a matrix  $A \in M^{n \times n}(\mathbb{R})$  is given by

$$p_A(\lambda) = \det(A - \lambda I). \quad (15)$$

**Theorem 1.**  $\lambda$  is an eigenvalue of  $A \iff p_A(\lambda) = \det(A - \lambda I) = 0$ .

Having found the eigenvalues  $\{\lambda_1, \dots, \lambda_n\}$  of  $A$ , we can substitute each of these in the equation

$$(A - \lambda_i I)v_i = 0 \quad (16)$$

to find the eigenvectors  $v_i$  associated with each eigenvalue  $\lambda_i$ , for  $i = 1, \dots, n$ . Having defined a process to compute eigenvectors and eigenvalues, we can start to delve into the spectral decomposition of a given matrix  $A \in M^{n \times n}(\mathbb{R})$ . We are given that  $AT = T\Lambda$ . It follows that,

$$AT = T\Lambda \iff A = T\Lambda T^{-1} \implies e^{At} = e^{T\Lambda T^{-1}t} \quad (17)$$

and therefore, we can rewrite (12) as

$$\mathbf{x}(t_0 + t) = Te^{At}T^{-1}\mathbf{x}(t_0). \quad (18)$$

The operator  $T^{-1}$  induces a transformation  $\mathbf{z} = T^{-1}\mathbf{x}$  into intrinsic eigenvector coordinates, in which we have decoupled dynamics,

$$\frac{d}{dt}\mathbf{z} = \Lambda\mathbf{z} \iff \frac{d}{dt}z_j = \lambda_j z_j, \quad \forall j. \quad (19)$$

## 2 Koopman Operator Theory

Koopman Operator Theory is an approach for the data-driven study of dynamical systems in terms of measurements  $\mathbf{g}(\mathbf{x})$  obtained from it.

In 1931, Koopman showed that it is possible to represent a non-linear dynamical system in terms of a linear but infinite-dimensional operator acting on a Hilbert space of state measurements. This operator is obviously called the **Koopman Operator**.

Before trying to understand Koopman Operator theory, let's study some important concepts.

**Definition 7 (Linear operator).** A *linear operator* is a mapping  $\alpha : M \rightarrow \mathbb{R}$  which satisfies

$$\alpha(\lambda x + \mu y) = \lambda \alpha(x) + \mu \alpha(y). \quad (20)$$

**Definition 8 ( $\mathcal{L}^p$ -space).** Let  $(X, \mathcal{A}, \mu)$  be a measure space and  $1 \leq p < \infty$ . The space  $\mathcal{L}^p(X)$  consists of equivalence classes of measurable functions  $f : X \rightarrow \mathbb{R}$  such that

$$\int_X |f|^p d\mu < \infty, \quad (21)$$

where 2 measurable functions are equivalent if they are equal  $\mu$ -a.e. The  $\mathcal{L}^p$ -norm is defined by

$$\|f\|_p = \left( \int_X |f|^p d\mu \right)^{\frac{1}{p}}. \quad (22)$$

If we consider  $\mathbb{N}$  with the counting measure we have the sequence space  $l^p(\mathbb{N})$ .

**Definition 9 ( $l^p$ -space).** The  $l^p$ -space is given by the space of all sequences  $\{x_n \in \mathbb{R}\}_{n \in \mathbb{N}}$ , such that

$$\sum_{n=1}^{\infty} |x_n|^p < \infty. \quad (23)$$

The  $l^p$ -norm is defined by

$$\|x\|_p = \left( \sum_{n=1}^{\infty} |x_n|^p \right)^{\frac{1}{p}}. \quad (24)$$

**Definition 10 (Cauchy sequence).** A *Cauchy sequence* is a sequence  $\{x_n\}_{n \in \mathbb{N}}$  such that

$$\forall \epsilon > 0, \exists N \in \mathbb{N} : m, n \geq N \implies d(x_n, x_m) < \epsilon. \quad (25)$$

**Definition 11.** A Hilbert space  $H$  is a complete inner product space. The inner product  $\langle \cdot, \cdot \rangle : H \times H \rightarrow \mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$  satisfies

1. *Conjugate symmetry:*  $\langle x, y \rangle = \overline{\langle y, x \rangle}$ ;
2. *Linearity in the first argument:*  $\langle ax + by, z \rangle = a \langle x, z \rangle + b \langle y, z \rangle$ ;

3. **Positive-definiteness:**  $\langle x, x \rangle > 0$ .

A Hilbert space  $H$  is complete in the sense that every Cauchy sequence in  $H$  is convergent.

## 2.1 Mathematical formulation of Koopman Theory

Since Koopman Operator Theory is a data-driven method, we should start by defining the data and how we will use it.

**Definition 12 (Observable).** An **observable** is a measurement function  $\mathbf{g} : M \rightarrow \mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$  of an infinite-dimensional Hilbert space. The space of measurement functions is denoted by  $\mathcal{G}(M) \subseteq \mathcal{C}(M)$ .

The Koopman Operator evolves the measurements of a dynamical system by means of the associated flow map.

**Definition 13 (Koopman Operator).** The **Koopman Operator** is an infinite-dimensional linear operator  $\mathcal{K}_t : \mathcal{C}(M) \rightarrow \mathcal{C}(M)$  that acts on observables in the following way

$$\mathcal{K}_t \mathbf{g}(\mathbf{x}) = \mathbf{g} \circ F_t(\mathbf{x}). \quad (26)$$

For a discrete-time dynamical system with timestep  $\Delta t$ , the Koopman propagator  $\mathcal{K}_{\Delta t}$  is defined by

$$\mathcal{K}_{\Delta t} \mathbf{g}(\mathbf{x}_k) = \mathbf{g}(F_{\Delta t}(\mathbf{x}_k)) = \mathbf{g}(\mathbf{x}_{k+1}), \quad (27)$$

and therefore, it defines an infinite-dimensional dynamical system that advances discrete state measurement  $\mathbf{g}(\mathbf{x}_k)$  for  $k \in \mathbb{N}$ .

The continuous analogue of

$$\mathbf{g}(\mathbf{x}_{k+1}) = \mathcal{K}_{\Delta t} \mathbf{g}(\mathbf{x}_k), \quad \left( \sim \mathbf{x}_{k+1} = F(\mathbf{x}_k) \right) \quad (28)$$

is given by the Lie operator  $\mathcal{L}$ , for which it holds

$$\frac{d}{dt} \mathbf{g} = \mathcal{L} \mathbf{g} \quad \left( \sim \frac{d}{dt} \mathbf{x}(t) = \mathbf{f}(\mathbf{x}(t)) \right). \quad (29)$$

Therefore,  $\mathcal{L}$  is the infinitesimal generator of the one-parameter family of transformations  $\mathcal{K}_t$ . By definition of derivative,  $\mathcal{L}$  is therefore given as

$$\mathcal{L} \mathbf{g} = \lim_{t \rightarrow 0} \frac{\mathcal{K}_t \mathbf{g} - \mathbf{g}}{t} = \lim_{t \rightarrow 0} \frac{\mathbf{g} \circ F_t - \mathbf{g}}{t}. \quad (30)$$

## 2.2 Koopman eigenfunctions and intrinsic coordinates

The Koopman Operator is linear but infinite-dimensional. Therefore, instead of capturing all the measurement functions on the Hilbert space, applied Koopman analysis tries to identify key measurement functions that evolve linearly with the flow. These are the eigenvectors of the Koopman operator, which enable globally linear representations of strongly non-linear dynamical systems.

**Definition 14 (Koopman eigenfunction).** We can define the **Koopman eigenfunction** for both continuous and discrete-time dynamical system with respect to the Lie operator  $\mathcal{L}$  and Koopman operator  $\mathcal{K}_t$ , respectively.

1. **Discrete-time Koopman Eigenfunction:**

$$\varphi(\mathbf{x}_{k+1}) = \mathcal{K}_t \varphi(\mathbf{x}_k) = e^{\lambda t} \varphi(\mathbf{x}_k); \quad (31)$$

This is equivalent to

$$\varphi(F_t(\mathbf{x}_k)) = e^{\lambda t} \varphi(\mathbf{x}_k). \quad (32)$$

Therefore, any such eigenfunction defines a coordinate evolving linearly along the flow of (4) and satisfying the linear ODE

$$\frac{d}{dt} \varphi(F_t(\mathbf{x}_k)) = \lambda \varphi(F_t(\mathbf{x}_k)). \quad (33)$$

Furthermore, we can create an analogous concept for a continuous-time dynamical system.

2. **Continuous-time Koopman Eigenfunction:**

$$\frac{d}{dt} \varphi(\mathbf{x}) = \mathcal{L} \varphi(\mathbf{x}) = \lambda \varphi(\mathbf{x}). \quad (34)$$

Applying the chain rule to the time derivative of  $\varphi(\mathbf{x})$  in equation (32), we get that

$$\frac{d}{dt} \varphi(\mathbf{x}) = \nabla \varphi(\mathbf{x}) \cdot \dot{\mathbf{x}} = \nabla \varphi(\mathbf{x}) \cdot \mathbf{f}(\mathbf{x}), \quad (35)$$

and by (34), it follows that

$$\nabla \varphi(\mathbf{x}) \cdot \dot{\mathbf{x}} = \lambda \varphi(\mathbf{x}). \quad (36)$$

Now, let's dive into some interesting properties of the Koopman eigenfunctions.

**Definition 15.** A **monoid** is a set  $M$  together with a binary operation  $\cdot$  which satisfies

1. **Associativity:**

$$(a \cdot b) \cdot c = a \cdot (b \cdot c), \quad \forall a, b, c \in M; \quad (37)$$

2. **Identity:**

$$\exists e_M \in M : e_M \circ a = a \circ e_M = a, \quad \forall a \in M. \quad (38)$$

Our goal now is to identify a monoidal structure on the set of Koopman eigenfunctions.

By definition of discrete-time Koopman eigenfunction,

$$\begin{aligned} \mathcal{K}_t(\varphi_1(\mathbf{x}_k) \varphi_2(\mathbf{x}_k)) &= \varphi_1(\mathbf{x}_{k+1}) \varphi_2(\mathbf{x}_{k+1}) = \lambda_1 \varphi_1(\mathbf{x}_k) \lambda_2 \varphi_2(\mathbf{x}_k) \\ &= \lambda_1 \lambda_2 \varphi_1(\mathbf{x}_k) \varphi_2(\mathbf{x}_k), \end{aligned} \quad (39)$$

and by definition of continuous-time Koopman eigenfunction,

$$\begin{aligned}\mathcal{L}(\varphi_1(\mathbf{x})\varphi_2(\mathbf{x})) &= \frac{d}{dt}(\varphi_1(\mathbf{x})\varphi_2(\mathbf{x})) = \frac{d}{dt}(\varphi_1(\mathbf{x}))\varphi_2(\mathbf{x}) + \varphi_1(\mathbf{x})\frac{d}{dt}(\varphi_2(\mathbf{x})) \\ &= \lambda_1\varphi_1(\mathbf{x})\varphi_2(\mathbf{x}) + \lambda_2\varphi_1(\mathbf{x})\varphi_2(\mathbf{x}) \\ &= (\lambda_1 + \lambda_2)\varphi_1(\mathbf{x})\varphi_2(\mathbf{x}).\end{aligned}\tag{40}$$

Therefore, the set of Koopman eigenfunctions  $\varphi = \{\varphi_i\}_{i \in I}$ , for  $I \subseteq \mathbb{N}$ , together with pointwise multiplication defined a monoid. The importance of this argument lies on the fact that for some dynamical systems, there may be a finite set of generator Koopman eigenvectors, i.e., Koopman eigenvectors which serve as basis for all others.

Applying the continuous-time limit definition (30) of the Koopman operator to the Koopman eigenfunction  $\varphi(\mathbf{x})$ , we get that

$$\begin{aligned}\mathcal{L}\varphi(\mathbf{x}) &= \lim_{t \rightarrow 0} \frac{\mathcal{K}_t\varphi(\mathbf{x}) - \varphi(\mathbf{x})}{t} = \lim_{t \rightarrow 0} \frac{e^{\lambda t}\varphi(\mathbf{x}) - \varphi(\mathbf{x})}{t} = \varphi(\mathbf{x}) \lim_{t \rightarrow 0} \frac{e^{\lambda t} - 1}{t} \\ &= \varphi(\mathbf{x}) \lim_{t \rightarrow 0} \lambda e^{\lambda t} = \lambda\varphi(\mathbf{x}).\end{aligned}\tag{41}$$

## 2.3 Koopman Mode Decomposition and finite representations

The multiple measurement functions  $\mathbf{g}_i : M \rightarrow \mathbb{F} \in \{\mathbb{R}, \mathbb{C}\}$  can be arranged in a column vector

$$\mathbf{g}(\mathbf{x}) = \begin{bmatrix} \mathbf{g}_1(\mathbf{x}) \\ \mathbf{g}_2(\mathbf{x}) \\ \vdots \\ \mathbf{g}_n(\mathbf{x}) \end{bmatrix}\tag{42}$$

Since the set of Koopman eigenfunctions  $\{\varphi_j(\mathbf{x})\}_{j \in \mathbb{N}}$  provides a basis for the Hilbert space, i.e.,  $\mathcal{L}^2(M) = \text{Lin}\{\varphi_j(\mathbf{x})\}$ , every individual measurement function can be expanded as

$$\mathbf{g}_i(\mathbf{x}) = \sum_{j=0}^{\infty} v_{ij}\varphi_j(\mathbf{x})\tag{43}$$

and it follows that

$$\mathbf{g}(\mathbf{x}) = \sum_{j=0}^{\infty} v_j\varphi_j(\mathbf{x}).\tag{44}$$

Now, the question is how to find Koopman modes. This is easily answered when we are dealing with conservative dynamical systems. Let's first derive the theory.

**Definition 16 (Measure).** A *measure*  $\mu$  on a measurable space  $(X, \Sigma)$  is a map  $\mu : \Sigma \rightarrow [-\infty, \infty]$  such that

1.  $\mu(\emptyset) = 0$ ;

2.  $\mu(A) \geq 0$ , for every  $A \in \Sigma$ ;
3. For all countable collections  $\{A_n\}_{n \in \mathbb{N}}$  of pairwise disjoint sets in  $\Sigma$ ,

$$\mu\left(\bigcup_{n=1}^{\infty} A_n\right) = \sum_{n=1}^{\infty} \mu(A_n). \quad (45)$$

A measure is  $\sigma$ -finite if  $X$  can be written as a countable union of measurable sets with finite measure.

**Definition 17 ( $\sigma$ -finite measure).** A measure  $\mu : \Sigma \rightarrow [-\infty, \infty]$  is  **$\sigma$ -finite** if

$$X = \bigcup_{n=1}^{\infty} A_n \text{ and } \mu(A_n) < \infty, \forall n \in \mathbb{N}. \quad (46)$$

**Definition 18 (Measurable map).** A **measurable map** is a map  $\tau : (X, \Sigma_X) \rightarrow (Y, \Sigma_Y)$  such that

$$\tau^{-1}(A) \in \Sigma_X, \forall A \in \Sigma_Y. \quad (47)$$

**Definition 19 (Measurable dynamical system).** A **measurable dynamical system** is a quadruple  $(X, \Sigma, \mu, \tau)$  such that  $(X, \Sigma)$  is a Borel space equipped with a sigma-finite measure  $\mu$  and a map  $\tau$ .

The map defines a single timestep transformation in the evolution of a dynamical system and we look into measurable maps so that the current state of a dynamical system comes from a well-defined past state.

**Definition 20 (Non-singular measurable map).** A measurable map  $\tau : X \rightarrow X$  is said to be **non-singular** if

$$\mu(\tau^{-1}(A)) = 0 \iff \mu(A) = 0, \forall A \in \Sigma. \quad (48)$$

The condition of being non-singular is essential for a dynamical system to be suitable for modelling.

**Definition 21 (Measure-preserving map).** A **measure-preserving map**  $\tau : X \rightarrow X$  is such that

$$\mu(\tau^{-1}(A)) = \mu(A), \forall A \in \Sigma. \quad (49)$$

A special type of measure-preserving map is a conservative map.

**Definition 22.** A **conservative map** is a map  $\tau : X \rightarrow X$  for which

$$\mu(A) > 0 \text{ and } \forall n \in \mathbb{N}, \exists p > n : \mu(A \cap \tau^{-p}(A)) > 0. \quad (50)$$

This means that a conservative dynamical system is one for which its current state revisits or comes arbitrarily close to a prior state.  
For conservative dynamical systems, the Koopman operator is unitary.

**Definition 23** (Unitary operator). *A unitary operator is an operator  $\mathcal{L}$  such that it satisfies*

1. **Boundedness:**  $\|\mathcal{L}\| < \infty$ ;
2. **Linearity:**  $\mathcal{L}(f + g) = \mathcal{L}(f) + \mathcal{L}(g)$ ;
3. **Unitary normality:**  $U^*U = UU^* = I$ .

It follows that the Koopman eigenfunctions are orthonormal and therefore, we can compute the Koopman modes by simply taking the projection of the Koopman Eigenfunctions onto the given measurement functions, i.e., each Koopman mode  $v_j$ ,  $j \in \mathbb{N}$  is given by

$$v_j = \begin{bmatrix} \langle \phi_j, \mathbf{g}_1 \rangle \\ \langle \phi_j, \mathbf{g}_2 \rangle \\ \vdots \\ \langle \phi_j, \mathbf{g}_p \rangle \end{bmatrix}. \quad (51)$$

We can now obtain another expression for the measurement function  $\mathbf{g}$  as follows

$$\begin{aligned} \mathbf{g}(\mathbf{x}_k) &= \mathcal{K}_t \mathbf{g}(\mathbf{x}_{k-1}) = \dots = \mathcal{K}_t^k \mathbf{g}(\mathbf{x}_0) = \mathcal{K}_t^k \sum_{j=0}^{\infty} v_j \varphi_j(\mathbf{x}_0) \\ &= \sum_{j=0}^{\infty} v_j \mathcal{K}_t^k \varphi_j(\mathbf{x}_0) = \sum_{j=0}^{\infty} v_j \lambda_j^k \varphi_j(\mathbf{x}_0). \end{aligned} \quad (52)$$

**Definition 24 (Koopman Mode Decomposition).** *The **Koopman Mode Decomposition** of the dynamical system  $\phi(t, x)$  with set of Koopman eigenfunctions  $\{\varphi_j(\mathbf{x})\}_{j \in \mathbb{N}}$  is given by the sequence of triples*

$$\{(\lambda_j, v_j, \varphi_j)\}_{j=0}^{\infty}. \quad (53)$$

## 2.4 Important eigenspaces and finite-dimensional models

The biggest challenge in modelling dynamical systems using the Koopman operator is the fact that the operator is infinite-dimensional. So, the idea is to find a finite-dimensional representation of the Koopman operator, which better approximates the dynamics. This can be done by finding finite-dimensional invariant subspaces.

**Definition 25 (Koopman invariant subspace).** *A **Koopman invariant subspace** is defined as the span of measurement functions  $\{g_1, g_2, \dots, g_p\}$  if all the functions in the subspace*

$$g = \alpha_1 g_1 + \alpha_2 g_2 + \dots + \alpha_p g_p = \sum_{i=1}^p \alpha_i g_i \quad (54)$$

*remain in this subspace after being acted by the Koopman operator  $\mathcal{K}$ .*

It is obvious that every finite set of eigenfunctions of the Koopman operator will span an invariant subspace and therefore, finding these eigenfunction coordinates is a central challenge in modelling since these provide intrinsic coordinates in which the dynamics behave linearly.

### 3 Non-recurrent sets and eigenfunctions

**Definition 26 (Non-recurrent set).** A *non-recurrent* set  $\Gamma \in M$  is one for which

$$\mathbf{x} \in \Gamma \implies F_t(\mathbf{x}) \notin \Gamma, \forall t \in (0, T]. \quad (55)$$

This basically means that the points lying on a non-recurrent set, when acted by the flow map, do not remain in the non-recurrent set.

We can define eigenfunctions  $\{\varphi_{\lambda, \mathbf{g}}\}$  on the entire image  $X_T$  of a non-recurrent set  $\Gamma$  by equating

$$\varphi_{\lambda, \mathbf{g}}(F_t(\mathbf{x}_0)) = e^{\lambda t} \mathbf{g}(\mathbf{x}_0). \quad (56)$$

**Definition 27 (Image of a non-recurrent set).** The *image*  $X_T$  of a *non-recurrent set*  $\Gamma$  is defined by

$$X_T = \bigcup_{t \in [0, T]} F_t(\Gamma) = \bigcup_{t \in [0, T]} \{F_t(\mathbf{x}_0) : \mathbf{x}_0 \in \Gamma\}. \quad (57)$$

In order to find a solution for the eigenfunction, we need to define the notion of a stopping time.

**Definition 28 (Hitting time).** The *hitting time* of  $\mathbf{x}$  in  $\Gamma$  is given by

$$\tau(\mathbf{x}) = \inf_{t \in \mathbb{R}} \{t : F_t(\mathbf{x}) \in \Gamma\} \quad (58)$$

We can therefore obtain an explicit expression for  $\varphi_{\lambda, \mathbf{g}}$  by flowing back until the hitting time of  $\mathbf{x}$  in  $\Gamma$ , i.e.,

$$\varphi_{\lambda, \mathbf{g}}(\mathbf{x}) = e^{-\lambda \tau(\mathbf{x})} \mathbf{g}(F_{\tau(\mathbf{x})}(\mathbf{x})). \quad (59)$$

**Theorem 2.** Let  $\Gamma$  be a non-recurrent set,  $g \in \mathcal{C}(M)$  and  $\lambda \in \mathbb{C}$ . Then  $\varphi_{\lambda, g}$  defined by (59) is a Koopman eigenfunction on  $X_T$ . It also satisfies the conditions (33) and (34) and if  $g$  is Lipschitz Continuous, it follows that

$$\nabla \varphi_{\lambda, g} \cdot f = \lambda \varphi_{\lambda, g}, \text{ a.e. } -X. \quad (60)$$

#### 3.1 Span of eigenfunctions

In this subsection, we show that it is possible to approximate any continuous function  $\mathbf{h} \in \mathcal{C}(X_T)$  with a linear combination of Koopman eigenfunctions  $\varphi_i$ , for  $i = 1, \dots, N$ .

**Definition 29 (Lattice of Koopman eigenvalues).** *The **lattice of Koopman eigenvalues**, denoted  $L(\Lambda)$ , is defined by*

$$L(\Lambda) = \left\{ \sum_{k=1}^p \alpha_k \lambda_k : \lambda_k \in \Lambda, \alpha_k \in \mathbb{N}, p \in \mathbb{N} \right\}. \quad (61)$$

Since  $L(\Lambda)$  is the set of all linear combinations of eigenvalues  $\lambda_k \in \Lambda$ , it follows trivially that if  $\Lambda$  is a set of eigenvalues, then so is  $L(\Lambda)$ . We can then define the set of all eigenfunctions arising from linear combinations of measurement functions  $\mathbf{g} \in \mathcal{G}(M)$  and eigenvalues in  $\Lambda$  as

$$\varphi_{\Lambda, \mathcal{G}(M)} = \{\varphi_{\lambda, \mathbf{g}} : \lambda \in \Lambda, \mathbf{g} \in \mathcal{G}(M)\}. \quad (62)$$

We now describe a way of approximating any continuous function  $\mathbf{h} \in \mathcal{C}(M)$  given a linear combination of Koopman eigenfunctions.

**Theorem 3.** *Let  $\Gamma$  be a non-recurrent set, closed in the standard topology of  $\mathbb{R}^n$  (euclidean topology) and let  $\Lambda_0 \subseteq \mathbb{C}$  be an arbitrary set of complex numbers such that at least one has a non-zero real part and  $\Lambda_0 = \bar{\Lambda}_0$ . Set  $\Lambda = L(\Lambda_0)$  and  $G = \{g_i\}_{i=1}^\infty$  be an arbitrary set of functions whose span is dense in  $\mathcal{C}(\Lambda)$  in the supremum norm. Then, the span of  $\varphi_{\Lambda, G}$  is dense in  $\mathcal{C}(X_T)$ , i.e., for every  $h \in \mathcal{C}(X_T)$  and any  $\epsilon > 0$  there exists  $\varphi_1, \dots, \varphi_N \in \varphi_{\Lambda, G}$  and  $c_1, \dots, c_N$  such that*

$$\sup_{\mathbf{x} \in X_T} \left| \mathbf{h}(\mathbf{x}) - \sum_{i=1}^N c_i \varphi_i(\mathbf{x}) \right| < \epsilon. \quad (63)$$
